THERMOSTABLE PHOSPHATASES

identified newly relates to invention This by such encoded polypeptides polynucleotides, the use of such polynucleotides and polynucleotides, polypeptides, as well as the production and isolation of such polynucleotides and polypeptides. More particularly, the polynucleotides and polypeptides of the present invention have been identified as thermostable alkaline phosphatases.

BACKGROUND OF THE INVENTION

Phosphatases are a group of enzymes that remove phosphate groups from organophosphate ester compounds. There are numerous phosphatases, including alkaline phosphatases, phosphodiesterases and phytases.

Alkaline phosphatases are widely distributed enzymes and are composed of a group of enzymes which hydrolyze organic phosphate ester bonds at alkaline pH.

Phosphodiesterases are capable of hydrolyzing nucleic acids by hydrolyzing the phosphodiester bridges of DNA and RNA. The classification of phosphodiesterases depends upon which side of the phosphodiester bridge is attacked. The 3' enzymes specifically hydrolyze the ester linkage between the 3' carbon and the phosphoric group whereas the 5' enzymes hydrolyze the ester linkage between the phosphoric group and the 5' carbon of the phosphodiester bridge. The best known of the class 3' enzymes is a phosphodiesterase from the venom of the rattlesnake or from a rustle's viper, which hydrolyses all the 3' bonds in either RNA or DNA liberating nearly all the nucleotide units as nucleotide 5' phosphates. This enzyme requires a free 3' hydroxyl group on the terminal nucleotide residue and proceeds stepwise from that end of the

polynucleotide chain. This enzyme and all other nucleases which attack only at the ends of the polynucleotide chains are called exonucleases. The 5' enzymes are represented by a phosphodiesterase from bovine spleen, also an exonuclease, which hydrolyses all the 5' linkages of both DNA and RNA and thus liberates only nucleoside 3' phosphates. It begins its attack at the end of the chain having a free 3' hydroxyl group.

Phytases are enzymes which recently have been introduced to commerce. The phytase enzyme removes phosphate from phytic acid (inositol hexaphosphoric acid), a compound found in plants such as corn, wheat and rice. The enzyme has commercial use for the treatment of animal feed, making the inositol of the phytic acid available for animal nutrition. Aspergillus ficuum and wheat are sources of phytase. (Business Communications Co., Inc., 25 Van Zant Street, Norwalk, CT 06855).

Phytase is used to improve the utilization of natural phosphorus in animal feed. Use of phytase as a feed additive enables the animal to metabolize a larger degree of its cereal feed's natural mineral content thereby reducing or altogether eliminating the need for synthetic phosphorus More important than the reduced need for additives. phosphorus additives is the corresponding reduction of phosphorus in pig and chicken waste. Many European countries severely limit the amount of manure that can be spread per acre due to concerns regarding phosphorus contamination of ground water. This is highly important in northern Europe, and will eventually be regulated throughout the remainder of the European Continent and the United States as well. (Excerpts from <u>Business Trend Analysts, Inc.</u>, January 1994, Frost and Sullivan Report 1995 and USDA on-line information.)

5.

Alkaline phosphatase hydrolyzes monophosphate esters, releasing an organic phosphate and the cognate alcohol compound. It is non-specific with respect to the alcohol moiety and it is this feature which accounts for the many uses of this enzyme. The enzyme has a pH optimum between 9 and 10, however, it can also function at neutral pH, (study of the enzyme industry conducted by Business Communications Company, Inc., 25 Van Zant Street, Norwalk, Connecticut 06855, 1995.).

PCT/US97/10784

Thermostable alkaline phosphatases are not irreversibly inactivated even when heated to 60°C or more for brief periods of time, as, for example, in the practice of hydrolyzing monophosphate esters.

Alkaline phosphatases may be obtained from numerous thermophilic organisms, such as Ammonifex degensii, Aquifex pyrophilus, Archaeoglobus lithotrophicus, Methanococcus Crenarchaeota), igneus, Pyrolobus(a Pyrococcus Thermococcus, which are mostly Eubacteria and Euryarchaeota. Many of these organisms grow at temperatures up to about 103°C and are unable to grow below 70°C. These anaerobes are isolated from extreme environments. For Thermococcus CL-2 was isolated from a worm residing on a "black smoker" sulfite structure.

Interest in alkaline phosphatases from thermophilic microbes has increased recently due to their value for commercial applications. Two sources of alkaline phosphatases dominate and compete commercially: (i) animal, from bovine and calf intestinal mucosa, and (ii) bacterial, from E. coli. Due to the high turnover number of calf intestinal phosphatase, it is often selected as the label in many enzyme immunoassays. The usefulness of calf alkaline phosphatase, however, is limited by its inherently low

.3

thermostability, which is even further compromised during the chemical preparation of the enzyme: antibody conjugates. Bacterial alkaline phosphatase is an alternative to calf alkaline phosphatase due to bacterial alkaline phosphatase's extreme thermotolerance at temperatures as high as 95°C (Tomazic-Allen, S.J., Recombinant Bacterial Phosphatase as an Immunodiagnostic Enzyme, Annals D Biology Clinique, 49(5):287-90 (1991), however, the enzyme has a very low turnover number.

There is a need for novel phosphatase enzymes having includes a need for This enhanced thermostability. alkaline whose enhanced thermostable phosphatases thermostability is beneficial in enzyme labeling processes and certain recombinant DNA techniques, such as in the dephosphorylation of vector DNA prior to insert DNA ligation. Recombinant phosphatase enzymes provide the proteins in a format amenable to efficient production of pure enzyme, which can be utilized in a variety of applications as described Accordingly, there is need herein. characterization, amino acid sequencing, DNA sequencing, and heterologous expression of thermostable phosphatase enzymes. The present invention meets these need by providing DNA and sequence information and exprssion purification protocol for thermostable phosphatase derived from several organisms.

SUMMARY OF THE INVENTION

The present invention provides thermostable phosphatases from several organisms. In accordance with one aspect of the present invention, there are provided novel enzymes, as well as active fragments, analogs and derivatives thereof.

In accordance with another aspect of the present invention, there are provided isolated nucleic acid molecules

PCT/US97/10784 WO 97/48416

ĸ.

encoding the enzymes of the present invention, including mRNAs, cDNAs, genomic DNAs, as well as active analogs and fragments of such nucleic acids.

In accordance with another aspect of the present invention, there are provided isolated nucleic acid molecules encoding mature enzymes expressed by the DNA contained in the plasmid DNA vector deposited with the ATCC as Deposit No. 97536 on May 10, 1996.

In accordance with a further aspect of the present invention, there is provided a process for producing such polypeptides by recombinant techniques comprising culturing recombinant prokaryotic and/or eukaryotic host cells, containing a nucleic acid sequence of the present invention, under conditions promoting expression of said enzymes and subsequent recovery of said enzymes.

In accordance with yet a further aspect of the present invention, there is provided a process for utilizing such enzymes for hydrolyzing monophosphate ester bonds, as an enzyme label in immunoassays, for removing 5' phosphate prior to end-labeling, and for dephosphorylating vectors prior to insert ligation.

In accordance with yet a further aspect of the present invention, there are also provided nucleic acid probes comprising nucleic acid molecules of sufficient length to specifically hybridize to a nucleic acid sequence of the present invention.

In accordance with yet a further aspect of the present invention, there is provided a process for utilizing such enzymes, or polynucleotides encoding such enzymes, for in vitro purposes related to scientific research, for example,

to generate probes for identifying similar sequences which might encode similar enzymes from other organisms by using certain regions, i.e., conserved sequence regions of the nucleotide sequence.

These and other aspects of the present invention will be apparent to those of skill in the art from the teachings herein.

Α

BRIEF DESCRIPTION OF THE DRAWINGS

The following drawings are illustrative of embodiments of the invention and are not meant to limit the scope of the invention as encompassed by the claims.

Figure 1 is an illustration of the full-length-DNA and corresponding deduced amino acid sequence of Ammonifex degensii KC4 of the present invention Sequencing was performed using a 378 automated DNA sequence for all sequences of the present invention (Applied Biosystems, Inc., Foster City, California).

Figure 2 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Methanococcus igneus Ko15. His IDNO: From 29, respectively)

Figure 3 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Thermococcus alcaliphilus AEDII12RA (Ed ID NC. 2) and E, respectively

Figure 4 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Thermococcus celer. (SEL ID NO: 22 and 3) Nespectively)

Figure 5 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Thermococcus GU5L5. (III II) NO.23 and 32, respectively)

Figure 6 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of OC9a LL II NO. 24 and 33, respectively

Figure 7 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of M11TL (H) INC 25 and 34, respectively)

Figure 8 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Thermococcus CL-2 (FL I) NC: 2 and 35)

Figure 9 is an illustration of the full-length DNA and corresponding deduced amino acid sequence of Aquifex VF-5 (Sed ID No. 2)

DETAILED DESCRIPTION OF THE INVENTION

To facilitate understanding of the invention, a number of terms are defined below.

The term "isolated" means altered "by the hand of man" from its natural state; i.e., if it occurs in nature, it has been changed or removed from its original environment, or both. For example, a naturally occurring polynucleotide or a polypeptide naturally present in a living animal in its natural state is not "isolated", but the same polynucleotide or polypeptide separated from the coexisting materials of its natural state is "isolated", as the term is employed herein. For example, with respect to polynucleotides, the term isolated means that it is separated from the nucleic acid and cell in which it naturally occurs.

Α.

As part of or following isolation, such polynucleotides can be joined to other polynucleotides, such as DNAs, for mutagenesis, to form fusion proteins, and for propagation or for instance. The isolated in a host, expression polynucleotides, alone or joined to other polynucleotides such as vectors, can be introduced into host cells, culture or in whole organisms. Introduced into host cells in culture or in whole organisms, such polynucleotides still would be isolated, as the term is used herein, because they in their naturally occurring be would not environment. Similarly, the polynucleotides and polypeptides may occur in a composition, such as a media formulation of polynucleotides introduction for polypeptides, for example, into cells or compositions or solutions for chemical or enzymatic reactions which are not naturally occurring compositions) and, therein remain isolated polynucleotides or polypeptides within the meaning of that term as it is employed herein.

The term "ligation" refers to the process of forming phosphodiester bonds between two or more polynucleotides, which most often are double stranded DNAs. Techniques for ligation are well known to the art and protocols for ligation are described in standard laboratory manuals and references, such as, for instance, Sambrook et al., MOLECULAR CLONING, A LABORATORY MANUAL, 2nd Ed.; Cold Spring Harbor Laboratory Press, Cold Spring Harbor, New York (1989).

The term "oligonucleotide" as used herein is defined as a molecule comprised of two or more deoxyribonucleotides or ribonucleotides, preferably more than three, and usually more than ten. The exact size of an oligonucleotide will depend on many factors, including the ultimate function or use of the oligonucleotide. Oligonucleotides can be prepared by any suitable method, including, for example, cloning and

4.

restriction of appropriate sequences and direct chemical synthesis by a method such as the phosphotriester method of Narang et al., 1979, Meth. Enzymol., 68:90-99; the phosphodiester method of Brown et al., 1979, Method Enzymol., 68:109-151, the diethylphosphoramidite method of Beaucage et al., 1981, Tetrahedron Lett., 22:1859-1862; the triester method of Matteucci et al., 1981, J. Am. Chem. Soc., 103:3185-3191, or automated synthesis methods; and the solid support method of U.S. Patent No. 4,458,066.

The term "plasmids" generally is designated herein by a lower case p preceded and/or followed by capital letters and/or numbers, in accordance with standard naming conventions that are familiar to those of skill in the art.

Plasmids disclosed herein are either commercially available, publicly available on an unrestricted basis, or can be constructed from available plasmids by routine application of well known, published procedures. Many plasmids and other cloning and expression vectors that can be used in accordance with the present invention are well known and readily available to those of skill in the art. Moreover, those of skill readily may construct any number of other plasmids suitable for use in the invention. The properties, construction and use of such plasmids, as well as other vectors, in the present invention will be readily apparent to those of skill from the present disclosure.

The term "polynucleotide(s)" generally refers to any polyribonucleotide or polydeoxyribonucleotide, which may be unmodified RNA or DNA or modified RNA or DNA. Thus, for instance, polynucleotides as used herein refers to, among others, single-and double-stranded DNA, DNA that is a mixture of single-and double-stranded regions, single- and double-stranded RNA, and RNA that is mixture of single- and double-stranded regions, hybrid molecules comprising DNA and RNA

5

that may be single-stranded or, more typically, doublestranded or a mixture of single- and double-stranded regions.

In addition, polynucleotide as used herein refers to triple-stranded regions comprising RNA or DNA or both RNA and DNA. The strands in such regions may be from the same molecule or from different molecules. The regions may include all of one or more of the molecules, but more typically involve only a region of some of the molecules. One of the molecules of a triple-helical region often is an oligonucleotide.

As used herein, the term polynucleotide includes DNAs or RNAs as described above that contain one or more modified bases. Thus, DNAs or RNAs with backbones modified for stability or for other reasons are "polynucleotides" as that term is intended herein. Moreover, DNAs or RNAs comprising unusual bases, such as inosine, or modified bases, such as tritylated bases, to name just two examples, are polynucleotides as the term is used herein.

It will be appreciated that a great variety of modifications have been made to DNA and RNA that serve many useful purposes known to those of skill in the art. The term polynucleotide as it is employed herein embraces such chemically, enzymatically or metabolically modified forms of polynucleotides, as well as the chemical forms of DNA and RNA characteristic of viruses and cells, including simple and complex cells, inter alia.

The term "primer" as used herein refers to an oligonucleotide, whether natural or synthetic, which is capable of acting as a point of initiation of synthesis when placed under conditions in which primer extension is initiated or possible. Synthesis of a primer extension product which is complementary to a nucleic acid strand is

Ł.

initiated in the presence of nucleoside triphosphates and a polymerase in an appropriate buffer at a suitable temperature.

The term "primer" may refer to more than one primer, particularly in the case where there is some ambiguity in the information regarding one or both ends of the target region to be synthesized. For instance, if a nucleic acid sequence is inferred from a protein sequence, a "primer" generated to synthesize nucleic acid encoding said protein sequence is actually a collection of primer oligonucleotides containing sequences representing all possible codon variations based on the degeneracy of the genetic code. One or more of the primers in this collection will be homologous with the end of the target sequence. Likewise, if a "conserved" region shows significant levels of polymorphism in a population, mixtures of primers can be prepared that will amplify adjacent sequences.

The term "restriction endonucleases" and "restriction enzymes" refers to bacterial enzymes which cut double-stranded DNA at or near a specific nucleotide sequence.

The term "gene" means the segment of DNA involved in producing a polypeptide chain; it includes regions preceding and following the coding region (leader and trailer) as well as intervening sequences (introns) between individual coding segments (exons).

A coding sequence is "operably linked" to another coding sequence when RNA polymerase will transcribe the two coding sequences into a single mRNA, which is then translated into a single polypeptide having amino acids derived from both coding sequences. The coding sequences need not be

Ţ

contiguous to one another so long as the expressed sequences ultimately process to produce the desired protein.

"Recombinant" enzymes refer to enzymes produced by recombinant DNA techniques; i.e., produced from cells transformed by an exogenous DNA construct encoding the desired enzyme. "Synthetic" enzymes are those prepared by chemical synthesis.

A DNA "coding sequence of" or a "nucleotide sequence encoding" a particular enzyme, is a DNA sequence which is transcribed and translated into an enzyme when placed under the control of appropriate regulatory sequences.

The term "thermostable phosphatase" refers to an enzyme which is stable to heat and heat-resistant and catalyzes the removal of phosphate groups from organophosphate ester compounds. Reference to "thermostable phosphatases" includes alkaline phosphatases, phosphodiesterases and phytases.

The phosphatase enzymes of the present invention cannot become irreversibly denatured (inactivated) when subjected to the elevated temperatures for the time necessary to effect the hydrolysis of a phosphate group from an organophosphate Irreversible denaturation for purposes ester compound. herein refers to permanent and complete loss of enzymatic activity. The phosphatase enzymes do not become irreversibly denatured from exposure to temperatures of a range from about 60°C to about 113°C or more. The extreme thermostability of the phosphatase enzymes provides additional advantages over previously characterized thermostable enzymes. Prior to the present invention, efficient hydrolysis of phosphate groups at temperatures as high as 100°C has not been demonstrated. No thermostable phosphatase has been described for this purpose.

-

In accordance with an aspect of the present invention, there are provided isolated nucleic acids (polynucleotides) which encode for the mature enzymes having the deduced amino acid sequences of Figures 1-9 (SEQ ID NOS:28-36).

In accordance with another aspect of the present invention, there are provided isolated polynucleotides encoding the enzymes of the present invention. The deposited material is a mixture of genomic clones comprising DNA encoding an enzyme of the present invention. Each genomic clone comprising the respective DNA has been inserted into a pBluescript vector (Stratagene, La Jolla, CA). The deposit has been deposited with the American Type Culture Collection, 12301 Parklawn Drive, Rockville, Maryland 20852, USA, on May 10, 1996 and assigned ATCC Deposit No. 97536.

The deposit(s) have been made under the terms of the Budapest Treaty on the International Recognition of the deposit of micro-organisms for purposes of patent procedure. The strains will be irrevocably and without restriction or condition released to the public upon the issuance of a patent. These deposits are provided merely as convenience to those of skill in the art and are not an admission that a deposit be required under 35 U.S.C. §112. The sequences of the polynucleotides contained in the deposited materials, as well as the amino acid sequences of the polypeptides encoded thereby, are controlling in the event of any conflict with any description of sequences herein. A license may be required to make, use or sell the deposited materials, and no such license is hereby granted.

The polynucleotides of this invention were originally recovered from genomic gene libraries derived from the following organisms:

Ammonifex degensii KC4 is a eubacteria from the genus Ammonifex. It was isolated in Java, Indonesia. It is a gram-negative, chemolithoautotroph. It grows optimally at $70\,^{\circ}$ C in a low-salt culture medium at pH 7 with 0.2% nitrate as a substrate and H_2/CO_2 in gas phase.

Methanococcus igneus KOL5 is a Euryarchaeota isolated from Kolbeinsey Ridge in the north of Iceland. It grows optimally at 85°C and pH 7.0 in a high-salt marine medium with $\rm H_2/CO_2$ in a gas phase. Aquifex pyrophilus KOL 5A is a marine bacteria isolated from th Kolbeinsey Ridge in the north of Iceland. It is a gram-negative, rod-shaped, strictly chemolithoautotrophic, knall gas bacterium, and a denitrifier. It grows optimally at 85°C in high-salt marine medium at pH 6.8 with $\rm O_2$ as a substrate and $\rm H_2/CO_2$ + 0.5% $\rm O_2$ in gas phase.

Thermococcus alcaliphilus AEDII12RA is from the genus Thermococcus. AEDII12RA grows optimally at 85°C, pH 9.5 in a high salt medium (marine) containing polysulfides and yeast extract as substrates and N_2 in gas phase.

Thermococcus celer is an Euryarchaeota. It grows optimally at 85°C and pH 6.0 in a high-salt marine medium containing elemental sulfur, yeast extract, and peptone as substrates and N_2 in gas phase.

Thermococcus GU5L5 is an Euryarchaeota isolated from the Guaymas Basin in Mexico. It grows optimally at 85°C and pH 6.0 in a high-salt marine medium containing 1% elemental sulfur, 0.4% yeast extract, and 0.5% peptone as substrates with N_2 in gas phase.

OC9a-27A3A is a bacteria of unknown etilogy obtained from Yellowstone National Park and maintained as a pure

٤

culture. It grows well on a TK6 medium and has cellulose degrader activity. Further, it codes for an alkaline phosphatase having greater than 50% polypeptide identity and greater than 32% polynucleotide identity to each of Bombyx mori and Escherichia coli C alkaline phosphatase precursors, which is significant homologyy. Thus, it is expectged that OC9a-27A3A can be cloned and expressed readily in Escherichi Coli C in place of its native alkaline phosphatase precursor.

M11 TL is a new species of Desulfurococcus isolated from Diamond Pool in Yellowstone National Park. M11TL grows heterotrophically by fermentation of different organic materials (sulfur is not necessary) and forms grape-like aggregates. The organism grows optimally at 85°C to 88°C and pH 7.0 in a low salt medium containing yeast extract, peptone, and gelatin as substrates with an N_2/CO_2 gas phase.

Thermococcus CL-2 is an Euryarchaeota isolated from the North Cleft Segment in the Juan de Fuca Ridge. It grows optimally at 88°C in a salt medium with an argon atmosphere.

Aquifex VF-5 is a marine bacteria isolated from a beach in Vulcano, Italy. It is a gram-negative, rod-shaped, strictly chemolithoautotrophic, knall gas bacterium. It grows optimally from 85-90°C in high-salt marine medium at pH 6.8, with O_2 as a substrate and H_2/CO_2 + 0.5% O_2 in gas phase.

Accordingly, the polynucleotides and enzymes encoded thereby are identified by the organism from which they were isolated, and are sometimes hereinafter referred to as "KC4" (Figure 1 and SEQ ID NOS:19 and 28), "Ko15" (Figure 2 and SEQ ID NOS:20 and 29), "AEDII12RA" (Figure 3 and SEQ ID NOS:21 and 30), "Celer" (Figure 4 and SEQ ID NOS:22 and 31), "GU5L5" (Figure 5 and SEQ ID NOS:23 and 32), "OC9a" (Figure 6 and SEQ ID NOS:24 and 33), "Ml1TL" (Figure 7 and SEQ ID NOS:25 and

34), "CL-2" (Figure 8 and SEQ ID NOS:26 and 35) and "VF-5" (Figure 9 and SEQ ID NOS:27 and 36).

The polynucleotides and polypeptides of the present invention show identity of the nucleotide and protein level to known genes and proteins encoded thereby as shown in Table 1.

3

Table 1

Clone	Gene/Protein with Closest Homology	Protein Identity	Nucleic Acid Identity
Ammonifex degensiii KC4-3A1A	Yarrowia lipolytica, Candida lipolytica, acid phosphatase	47 %	24%
Ammonifex degensii KC4-3A1A	Saccharomyces cerevisiae, hypothetical protein YBR094w	54%	26%
Methanococcus igeneus Kol5-9A1A	Yarrowia lipolytica, Candida lipolytica, acid phosphatase	45%	25%
Methanococcus igeneus Kol5-9A1A	Saccharomyces cerevisiae, hypothetical protein YBR094w, hypothetical protein YBR0821	52%	25%
Thermococcus alcaliphilus AEDII12RA-18A	No homology found		
Thermococus celer 25A1A	No homology found		
Thermococcus GU5L5- 26A1A	Bacillius subtilis, alkaline phosphatase IV precursor, alkaline phosphomonoesterase, glycerophosphatase, and phosphomonoesterase	58%	38%
Thermococcus GU5L5- 26A1A	Bacillius subtilis, alkaline phosphatase III precursor	58%	37%
OC9a-27A3A	Bombyx mori (silkworm), alkaline phosphatase precursor	54%	33%
OC9a - 27A3A	Escherichia coli C, alkaline phosphatase precursor	53%	34%
M11 TL - 29A1A	Rhodobacter capsulatus, hypothetical protein B	43 %	24%
Thermococcus C12-30A1A	Yarrowia lipolytica, Candida lipolytica, acid phosphatase	49%	27 %
Thermococcus CL2-30A1A	Saccharomyces cerevisiae, hypothetical protein YBR094w hypothetical protein YBR0821	50%	25%
Aquifex VF5-34A1A	Escherichia coli, suppressor protein suhB	57 %	34 %

All of the clones identified in Table 1 encode polypeptides which have phosphatase activity.

One means for isolating the nucleic acid molecules encoding the enzymes of the present invention is to probe a gene library with a natural or artificially designed probe using art recognized procedures (see, for example: Current Protocols in Molecular Biology, Ausubel F.M. et al. (EDS.) Green Publishing Company Assoc. and John Wiley Interscience, New York, 1989, 1992). It is appreciated by one skilled in the art that the polynucleotides of SEQ ID NOS: 1-18, or fragments thereof (comprising at least 12 contiguous nucleotides), are particularly useful probes. Other particularly useful probes for this purpose are hybridizable fragments of the sequences of SEQ ID NOS: 19-27 (i.e., comprising at least 12 contiguous nucleotides).

With respect to nucleic acid sequences which hybridize to specific nucleic acid sequences disclosed herein, hybridization may be carried out under conditions of reduced stringency, medium stringency or even stringent conditions. As an example of oligonucleotide hybridization, a polymer membrane containing immobilized denatured nucleic acids is first prehybridized for 30 minutes at 45°C in a solution consisting of 0.9 M NaCl, 50 mM NaH₂PO₄, pH 7.0, 5.0 mM 10X Denhardt's, and 0.5 Na, EDTA, 0.5% SDS, polyriboadenylic acid. Approximately 2 X 107 cpm (specific activity 4-9 X 108 cpm/ug) of 32P end-labeled oligonucleotide probe are then added to the solution. After 12-16 hours of incubation, the membrane is washed for 30 minutes at room temperature in 1X SET (150 mM NaCl, 20 mM Tris hydrochloride, pH 7.8, 1 mM Na₂EDTA) containing 0.5% SDS, followed by a 30 minute wash in fresh IX SET at (Tm less 10°C) for the oligonucleotide probe. The membrane is then exposed to autoradiographic film for detection of hybridization signals.

1

Stringent conditions means hybridization will occur only if there is at least 90% identity, preferably at least 95% identity and most preferably at least 97% identity between the sequences. Further, it is understood that a section of a 100 bps sequence that is 95 bps in length has 95% identity with the 1090 bps sequence from which it is obtained. See J. Sambrook et al., Molecular Cloning, A Laboratory Manual, 2d Ed., Cold Spring Harbor Laboratory (1989) which is hereby incorporated by reference in its entirety. Also, it is understood that a fragment of a 100 bps sequence that is 95 bps in length has 95% identity with the 100 bps sequence from which it is obtained.

As used herein, a first DNA (RNA) sequence is at least 70% and preferably at least 80% identical to another DNA (RNA) sequence if there is at least 70% and preferably at least a 80% or 90% identity, respectively, between the bases of the first sequence and the bases of the another sequence, when properly aligned with each other, for example when aligned by BLASTN.

The present invention relates to polynucleotides which differ from the reference polynucleotide such that the differences are silent, for example, the amino acid sequence encoded by the polynucleotides is the same. The present invention also relates to nucleotide changes which result in amino acid substitutions, additions, deletions, fusions and truncations in the polypeptide encoded by the reference polynucleotide. In a preferred aspect of the invention these polypeptides retain the same biological action as the polypeptide encoded by the reference polynucleotide.

The polynucleotides of this invention were recovered from genomic gene libraries from the organisms listed in Table 1. Gene libraries were generated from either of a

Lambda ZAP II or a pBluscript] cloning vector (Stratagene Cloning Systems). Mass excisions were performed on these libraries to generate libraries in the pBluescript phagemid. Libraries were generated and excisions were performed according to the protocols/methods hereinafter described.

٤

The polynucleotides of the present invention may be in the form of RNA or DNA which DNA includes cDNA, genomic DNA, and synthetic DNA. The DNA may be double-stranded or single-stranded, and if single stranded may be the coding strand or non-coding (anti-sense) strand. The coding sequences which encodes the mature enzymes may be identical to the coding sequences shown in Figures 1-9 (SEQ ID NOS: 19-27) or may be a different coding sequence which coding sequence, as a result of the redundancy or degeneracy of the genetic code, encodes the same mature enzymes as the DNA of Figures 1-9 (SEQ ID NOS: 19-27).

The polynucleotide which encodes for the mature enzyme of Figures 1-9 (SEQ ID NOS: 28-36) may include, but is not limited to: only the coding sequence for the mature enzyme; the coding sequence for the mature enzyme and additional coding sequence such as a leader sequence or a proprotein sequence; the coding sequence for the mature enzyme (and optionally additional coding sequence) and non-coding sequence, such as introns or non-coding sequence 5' and/or 3' of the coding sequence for the mature enzyme.

Thus, the term "polynucleotide encoding an enzyme (protein)" encompasses a polynucleotide which includes only coding sequence for the enzyme as well as a polynucleotide which includes additional coding and/or non-coding sequence.

The present invention further relates to variants of the hereinabove described polynucleotides which encode for

fragments, analogs and derivatives of the enzymes having the deduced amino acid sequences of Figures 1-9 (SEQ ID NOS: 28-36). The variant of the polynucleotide may be a naturally occurring allelic variant of the polynucleotide or a non-naturally occurring variant of the polynucleotide.

Thus, the present invention includes polynucleotides encoding the same mature enzymes as shown in Figures 1-9 (SEQ ID NOS: 19-27) as well as variants of such polynucleotides which variants encode for a fragment, derivative or analog of the enzymes of Figures 1-9 (SEQ ID NOS: 19-27). Such nucleotide variants include deletion variants, substitution variants and addition or insertion variants.

As hereinabove indicated, the polynucleotides may have a coding sequence which is a naturally occurring—allelic variant of the coding sequences shown in Figures 1-9 (SEQ ID NOS: 19-27). As known in the art, an allelic variant is an alternate form of a polynucleotide sequence which may have a substitution, deletion or addition of one or more nucleotides, which does not substantially alter the function of the encoded enzyme. Also, using directed and other evolution strategies, one may make very minor changes in DNA sequence which can result in major changes in function.

Fragments of the full length gene of the present invention may be used as hybridization probes for a cDNA or a genomic library to isolate the full length DNA and to isolate other DNAs which have a high sequence similarity to the gene or similar biological activity. Probes of this type preferably have at least 10, preferably at least 15, and even more preferably at least 30 bases and may contain, for example, at least 50 or more bases. In fact, probes of this type having at least up to 150 bases or greater may be preferably utilized. The probe may also be used to identify

a DNA clone corresponding to a full length transcript and a genomic clone or clones that contain the complete gene including regulatory and promotor regions, exons and introns. An example of a screen comprises isolating the coding region of the gene by using the known DNA sequence to synthesize an oligonucleotide probe. Labeled oligonucleotides having a sequence complementary or identical to that of the gene or portion of the gene sequences of the present invention are used to screen a library of genomic DNA to determine which members of the library the probe hybridizes to.

It is also appreciated that such probes can be and are preferably labeled with an analytically detectable reagent to facilitate identification of the probe. Useful reagents include but are not limited to radioactivity, fluorescent dyes or enzymes capable of catalyzing the formation of a detectable product. The probes are thus useful to isolate complementary copies of DNA from other sources or to screen such sources for related sequences.

invention further relates present The polynucleotides which hybridize to the hereinabove-described sequences if there is at least 70%, preferably at least 90%, and more preferably at least 95% identity between the (As indicated above, 70% identity would include within such definition a 70 bps fragment taken from a 100 bp polynucleotide, for example.) The present particularly relates to polynucleotides which hybridize under to the hereinabove-described conditions stringent polynucleotides. As herein used, the term "stringent conditions" means hybridization will occur only if there is at least 95% and preferably at least 97% identity between the The polynucleotides which hybridize to the sequences. hereinabove described polynucleotides in a preferred embodiment encode enzymes which either retain substantially the same biological function or activity as the mature enzyme encoded by the DNA of Figures 1-9 (SEQ ID NOS: 19-27). In referring to identity in the case of hybridization, as known in the art, such identity refers to the complementarity of two polynucleotide segments.

Alternatively, the polynucleotide may have at least 15 bases, preferably at least 30 bases, and more preferably at least 50 bases which hybridize to any part of a polynucleotide of the present invention and which has an identity thereto, as hereinabove described, and which may or may not retain activity. For example, such polynucleotides may be employed as probes for the polynucleotides of SEQ ID NOS: 19-27, for example, for recovery of the polynucleotide or as a diagnostic probe or as a PCR primer.

Thus, the present invention is directed polynucleotides having at least a 70% identity, preferably at least 90% identity and more preferably at least a 95% identity to a polynucleotide which encodes the enzymes of SEO ID NOS: 28-36 as well as fragments thereof, which fragments have at least 15 bases, preferably at least 30 bases, more preferably at least 50 bases and most preferably fragments having up to at least 150 bases or greater, which fragments are at least 90% identical, preferably at least 95% identical and most preferably at least 97% identical to any portion of a polynucleotide of the present invention.

The present invention further relates to enzymes which have the deduced amino acid sequences of Figures 1-9 (SEQ ID NOS: 28-36) as well as fragments, analogs and derivatives of such enzyme.

The terms "fragment," "derivative" and "analog" when referring to the enzymes of Figures 1-9 (SEQ ID NOS. 28-36)

means enzymes which retain essentially the same biological function or activity as such enzymes. Thus, an analog includes a proprotein which can be activated by cleavage of the proprotein portion to produce an active mature enzyme.

The enzymes of the present invention may be a recombinant enzyme, a natural enzyme or a synthetic enzyme, preferably a recombinant enzyme.

fragment, derivative or analog of the enzymes of Figures 1-9 (SEQ ID NOS.28-36) may be (i) one in which one or more of the amino acid residues are substituted with a conserved or non-conserved amino acid residue (preferably a conserved amino acid residue) and such substituted amino acid residue may or may not be one encoded by the genetic code, or (ii) one in which one or more of the amino acid residues includes a substituent group, or (iii) one in which the mature enzyme is fused with another compound, such as a compound to increase the half-life of the enzyme (for example, polyethylene glycol), or (iv) one in which the additional amino acids are fused to the mature enzyme, such as a leader or secretory sequence or a sequence which is employed for purification of the mature enzyme proprotein sequence. Such fragments, derivatives and analogs are deemed to be within the scope of those skilled in the art from the teachings herein.

The enzymes and polynucleotides of the present invention are preferably provided in an isolated form, and preferably are purified to homogeneity.

The term "isolated" means that the material is removed from its original environment (e.g., the natural environment if it is naturally occurring). For example, a naturallyoccurring polynucleotide or enzyme present in a living animal the same polynucleotide or enzyme, all of the coexisting materials in the plated. Such polynucleotides could be such polynucleotides or enzymes could on, and still be isolated in that such is not part of its natural environment.

e present invention include the enzymes (in particular the mature enzyme) as which have at least 70% similarity 70% identity) to the enzymes of SEQ ID referably at least 90% similarity (more 70% identity) to the enzymes of SEQ ID more preferably at least 95% similarity at least 95% identity) to the enzymes of and also include portions of such also include portions of such also and more preferably at least 50 amino ably at least up to 150 amino acids.

art "similarity" between two enzymes is ring the amino acid sequence and its d substitutes of one enzyme to the ond enzyme. The definition of 70% ude a 70 amino acid sequence fragment of ruence, for example, or a 70 amino acid sequentially or randomly deleting 30 100 amino acid sequence.

a "fragment", "analog" or "derivative" ierence polypeptide may differ in amino ne or more substitutions, additions, and truncations, which may be present in

Among preferred variants are those that vary from a reference by conservative amino acid substitutions. Such substitutions are those that substitute a given amino acid in a polypeptide by another amino acid of like characteristics. Typically seen as conservative substitutions are the replacements, one for another, among the aliphatic amino acids Ala, Val, Leu and Ile; interchange of the hydroxyl residues Ser and Thr, exchange of the acidic residues Asp and Glu, substitution between the amide residues Asn and Gln, exchange of the basic residues Lys and Arg and replacements among the aromatic residues Phe, Tyr.

Most highly preferred are variants which retain the same biological function and activity as the reference polypeptide from which it varies.

Fragments or portions of the enzymes of the present invention may be employed for producing the corresponding full-length enzyme by peptide synthesis; therefore, the fragments may be employed as intermediates for producing the full-length enzymes. Fragments or portions of the polynucleotides of the present invention may be used to synthesize full-length polynucleotides of the present invention.

The present invention also relates to vectors which include polynucleotides of the present invention, host cells which are genetically engineered with vectors of the invention and the production of enzymes of the invention by recombinant techniques.

Host cells are genetically engineered (transduced or transformed or transfected) with the vectors of this invention which may be, for example, a cloning vector such as an expression vector. The vector may be, for example, in the

form of a plasmid, a phage, etc. The engineered host cells can be cultured in conventional nutrient media modified as appropriate for activating promoters, selecting transformants or amplifying the genes of the present invention. The culture conditions, such as temperature, pH and the like, are those previously used with the host cell selected for expression, and will be apparent to the ordinarily skilled artisan.

The polynucleotides of the present invention may be employed for producing enzymes by recombinant techniques. Thus, for example, the polynucleotide may be included in any one of a variety of expression vectors for expressing an enzyme. Such vectors include chromosomal, nonchromosomal and synthetic DNA sequences, e.g., derivatives of SV40; bacterial plasmids; phage DNA; baculovirus; yeast plasmids; vectors derived from combinations of plasmids and phage DNA, viral DNA such as vaccinia, adenovirus, fowl pox virus, and pseudorabies. However, any other vector may be used as long as it is replicable and viable in the host.

The appropriate DNA sequence may be inserted into the vector by a variety of procedures. In general, the DNA sequence is inserted into an appropriate restriction endonuclease site(s) by procedures known in the art. Such procedures and others are deemed to be within the scope of those skilled in the art.

The DNA sequence in the expression vector is operatively linked to an appropriate expression control sequence(s) (promoter) to direct mRNA synthesis. As representative examples of such promoters, there may be mentioned: LTR or SV40 promoter, the $E.\ coli.\ lac$ or trp, the phage lambda P_L promoter and other promoters known to control expression of genes in prokaryotic or eukaryotic cells or their viruses.

The expression vector also contains a ribosome binding site for translation initiation and a transcription terminator. The vector may also include appropriate sequences for amplifying expression.

In addition, the expression vectors preferably contain one or more selectable marker genes to provide a phenotypic trait for selection of transformed host cells such as dihydrofolate reductase or neomycin resistance for eukaryotic cell culture, or such as tetracycline or ampicillin resistance in E. coli.

The vector containing the appropriate DNA sequence as hereinabove described, as well as an appropriate promoter or control sequence, may be employed to transform an appropriate host to permit the host to express the protein.

As representative examples of appropriate hosts, there may be mentioned: bacterial cells, such as E. coli, Streptomyces, Bacillus subtilis; fungal cells, such as yeast; insect cells such as Drosophila S2 and Spodoptera Sf9; animal cells such as CHO, COS or Bowes melanoma; adenoviruses; plant cells, etc. The selection of an appropriate host is deemed to be within the scope of those skilled in the art from the teachings herein.

More particularly, the present invention also includes recombinant constructs comprising one or more of the sequences as broadly described above. The constructs comprise a vector, such as a plasmid or viral vector, into which a sequence of the invention has been inserted, in a forward or reverse orientation. In a preferred aspect of this embodiment, the construct further comprises regulatory sequences, including, for example, a promoter, operably linked to the sequence. Large numbers of suitable vectors

and promoters are known to those of skill in the art, and are commercially available. The following vectors are provided by way of example; Bacterial: pQE70, pQE60, pQE-9 (Qiagen), pBluescript II KS, ptrc99a, pKK223-3, pDR540, pRIT2T-(Pharmacia); Eukaryotic: pXT1, pSG5 (Stratagene) pSVK3, pBPV, pMSG, pSVL SV40 (Pharmacia). However, any other plasmid or vector may be used as long as they are replicable and viable in the host.

Promoter regions can be selected from any desired gene using CAT (chloramphenical transferase) vectors or other vectors with selectable markers. Two appropriate vectors are pKK232-8 and pCM7. Particular named bacterial promoters include lacI, lacZ, T3, T7, gpt, lambda $P_{\rm R}$, $P_{\rm L}$ and trp. Eukaryotic promoters include CMV immediate early, HSV thymidine kinase, early and late SV40, LTRs from retrovirus, and mouse metallothionein-I. Selection of the appropriate vector and promoter is well within the level of ordinary skill in the art.

In a further embodiment, the present invention relates to host cells containing the above-described constructs. The host cell can be a higher eukaryotic cell, such as a mammalian cell, or a lower eukaryotic cell, such as a yeast cell, or the host cell can be a prokaryotic cell, such as a bacterial cell. Introduction of the construct into the host cell can be effected by calcium phosphate transfection, DEAE-Dextran mediated transfection, or electroporation (Davis, L., Dibner, M., Battey, I., Basic Methods in Molecular Biology, (1986)).

The constructs in host cells can be used in a conventional manner to produce the gene product encoded by the recombinant sequence. Alternatively, the enzymes of the

invention can be synthetically produced by conventional peptide synthesizers.

Mature proteins can be expressed in mammalian cells, yeast, bacteria, or other cells under the control of appropriate promoters. Cell-free translation systems can also be employed to produce such proteins using RNAs derived from the DNA constructs of the present invention. Appropriate cloning and expression vectors for use with prokaryotic and eukaryotic hosts are described by Sambrook et al., Molecular Cloning: A Laboratory Manual, Second Edition, Cold Spring Harbor, N.Y., (1989), the disclosure of which is hereby incorporated by reference.

Transcription of the DNA encoding the enzymes of the present invention by higher eukaryotes is increased by inserting an enhancer sequence into the vector. Enhancers are cis-acting elements of DNA, usually about from 10 to 300 bp that act on a promoter to increase its transcription. Examples include the SV40 enhancer on the late side of the replication origin bp 100 to 270, a cytomegalovirus early promoter enhancer, the polyoma enhancer on the late side of the replication origin, and adenovirus enhancers.

Generally, recombinant expression vectors will include origins of replication and selectable markers permitting transformation of the host cell, e.g., the ampicillin resistance gene of E. coli and S. cerevisiae TRP1 gene, and a promoter derived from a highly-expressed gene to direct transcription of a downstream structural sequence. Such promoters can be derived from operons encoding glycolytic enzymes such as 3-phosphoglycerate kinase (PGK), α -factor, acid phosphatase, or heat shock proteins, among others. The heterologous structural sequence is assembled in appropriate phase with translation initiation and termination sequences,

and preferably, a leader sequence capable of directing secretion of translated enzyme. Optionally, the heterologous sequence can encode a fusion enzyme including an N-terminal identification peptide imparting desired characteristics, e.g., stabilization or simplified purification of expressed recombinant product.

Useful expression vectors for bacterial use are constructed by inserting a structural DNA sequence encoding a desired protein together with suitable translation initiation and termination signals in operable reading phase with a functional promoter. The vector will comprise one or more phenotypic selectable markers and an origin of replication to ensure maintenance of the vector and to, if desirable, provide amplification within the host. Suitable prokaryotic hosts for transformation include E: coli, Bacillus subtilis, Salmonella typhimurium and various species within the genera Pseudomonas, Streptomyces, and Staphylococcus, although others may also be employed as a matter of choice.

As a representative but nonlimiting example, useful expression vectors for bacterial use can comprise a selectable marker and bacterial origin of replication derived from commercially available plasmids comprising genetic elements of the well known cloning vector pBR322 (ATCC 37017). Such commercial vectors include, for example, pKK223-3 (Pharmacia Fine Chemicals, Uppsala, Sweden) and pGEM1 (Promega Biotec, Madison, WI, USA). These pBR322 "backbone" sections are combined with an appropriate promoter and the structural sequence to be expressed.

Following transformation of a suitable host strain and growth of the host strain to an appropriate cell density, the selected promoter is induced by appropriate means (e.g.,

temperature shift or chemical induction) and cells are cultured for an additional period.

Cells are typically harvested by centrifugation, disrupted by physical or chemical means, and the resulting crude extract retained for further purification.

Microbial cells employed in expression of proteins can be disrupted by any convenient method, including freeze-thaw cycling, sonication, mechanical disruption, or use of cell lysing agents, such methods are well known to those skilled in the art.

Various mammalian cell culture systems can also be employed to express recombinant protein. Examples of mammalian expression systems include the COS-7 lines of monkey kidney fibroblasts, described by Gluzman, Cell, 23:175 (1981), and other cell lines capable of expressing a compatible vector, for example, the C127, 3T3, CHO, HeLa and BHK cell lines. Mammalian expression vectors will comprise an origin of replication, a suitable promoter and enhancer, also any necessary ribosome binding polyadenylation site, splice donor and acceptor sites, transcriptional termination sequences, and 5' flanking nontranscribed sequences. DNA sequences derived from the SV40 splice, and polyadenylation sites may be used to provide the required nontranscribed genetic elements.

The enzyme can be recovered and purified from recombinant cell cultures by methods including ammonium sulfate or ethanol precipitation, acid extraction, anion or cation exchange chromatography, phosphocellulose chromatography, hydroxylapatite chromatography and lectin chromatography. Protein refolding steps can be used,

as necessary, in completing configuration of the mature protein. Finally, high performance liquid chromatography (HPLC) can be employed for final purification steps.

The enzymes of the present invention may be a naturally purified product, or a product of chemical synthetic procedures, or produced by recombinant techniques from a prokaryotic or eukaryotic host (for example, by bacterial, yeast, higher plant, insect and mammalian cells in culture). Depending upon the host employed in a recombinant production procedure, the enzymes of the present invention may be glycosylated or may be non-glycosylated. Enzymes of the invention may or may not also include an initial methionine amino acid residue.

Phosphatases are a group of key enzymes in the removal of phosphate groups from organophosphate ester compounds. There are numerous phosphatases, including alkaline phosphatases, phosphodiesterases and phytases.

The general application and definitions of such compounds are discussed above under the background of the invention section.

The present invention provides novel phosphatase enzymes having enhanced thermostability. Such phosphatases are beneficial in enzyme labeling processes and in certain recombinant DNA techniques, such as in the dephosphorylation of vector DNA prior to insert DNA ligation. The recombinant phosphatase enzymes provide the proteins in a format amenable to efficient production of pure enzyme, which can be utilized in a variety of applications as described herein.

Antibodies generated against the enzymes corresponding to a sequence of the present invention can be obtained by direct injection of the enzymes into an animal or by

administering the enzymes to an animal, preferably a nonhuman. The antibody so obtained will then bind the enzymes itself. In this manner, even a sequence encoding only a fragment of the enzymes can be used to generate-antibodies binding the whole native enzymes. Such antibodies can then be used to isolate the enzyme from cells expressing that enzyme.

For preparation of monoclonal antibodies, any technique which provides antibodies produced by continuous cell line cultures can be used. Examples include the hybridoma technique (Kohler and Milstein, Nature, 256:495-497, 1975), the trioma technique, the human B-cell hybridoma technique (Kozbor et al., Immunology Today 4:72, 1983), and the EBV-hybridoma technique to produce human monoclonal antibodies (Cole et al., in Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96, 1985).

Techniques described for the production of single chain antibodies (U.S. Patent 4,946,778) can be adapted to produce single chain antibodies to immunogenic enzyme products of this invention. Also, transgenic mice may be used to express humanized antibodies to immunogenic enzyme products of this invention.

Antibodies generated against an enzyme of the present invention may be used in screening for similar enzymes from other organisms and samples. Such screening techniques are known in the art, for example, one such screening assay is described in Sambrook and Maniatis, Molecular Cloning: A Laboratory Manual (2d Ed.), vol. 2:Section 8.49, Cold Spring Harbor Laboratory, 1989, which is hereby incorporated by reference in its entirety.

The present invention will be further described with reference to the following examples; however, it is to be understood that the present invention is not limited to such examples. All parts or amounts, unless otherwise specified, are by weight.

In order to facilitate understanding of the following examples certain frequently occurring methods and/or terms will be described.

"Plasmids" are designated by a lower case "p" preceded and/or followed by capital letters and/or numbers. The starting plasmids herein are either commercially available, publicly available on an unrestricted basis, or can be constructed from available plasmids in accord with published procedures. In addition, equivalent plasmids to those described are known in the art and will be apparent to the ordinarily skilled artisan.

"Digestion" of DNA refers to catalytic cleavage of the DNA with a restriction enzyme that acts only at certain sequences in the DNA. The various restriction enzymes used herein are commercially available and their reaction conditions, cofactors and other requirements were used as would be known to the ordinarily skilled artisan. analytical purposes, typically 1 μg of plasmid or DNA fragment is used with about 2 units of enzyme in about 20 μ l of buffer solution. For the purpose of isolating DNA fragments for plasmid construction, typically 5 to 50 μg of DNA are digested with 20 to 250 units of enzyme in a larger volume. Appropriate buffers and substrate amounts for particular restriction enzymes are specified manufacturer. Incubation times of about 1 hour at 37°C are ordinarily used, but may vary in accordance with the supplier's instructions. After digestion the reaction is electrophoresed directly on a polyacrylamide gel to isolate the desired fragment.

Size separation of the cleaved fragments is performedusing 8 percent polyacrylamide gel described by Goeddel et al., Nucleic Acids Res., 8:4057 (1980).

"Oligonucleotides" refers to either a single stranded polydeoxynucleotide or two complementary polydeoxynucleotide strands which may be chemically synthesized. Such synthetic oligonucleotides have no 5' phosphate and thus will not ligate to another oligonucleotide without adding a phosphate with an ATP in the presence of a kinase. A synthetic oligonucleotide will ligate to a fragment that has not been dephosphorylated.

"Ligation" refers to the process of forming phosphodiester bonds between two double stranded nucleic acid fragments (Maniatis, T., et al., Id., p. 146). Unless otherwise provided, ligation may be accomplished using known buffers and conditions with 10 units of T4 DNA ligase ("ligase") per 0.5 μg of approximately equimolar amounts of the DNA fragments to be ligated.

Unless otherwise stated, transformation was performed as described in Sambrook and Maniatis, Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory, 1989.

One means for isolating the nucleic acid molecules encoding the enzymes of the present invention is to probe a gene library with a natural or artificially designed probe using art recognized procedures (see, for example: Current Protocols in Molecular Biology, Ausubel F.M. et al. (EDS.) Green Publishing Company Assoc. and John Wiley Interscience,

New York, 1989, 1992). It is appreciated to one skilled in the art that the polynucleotides of SEQ ID NOS:1-16, or fragments thereof (comprising at least 10 or 12 contiguous nucleotides), are particularly useful probes. Other particularly useful probes for this purpose are fragments hybridizable fragments to the sequences of SEQ ID NOS:19-27 (i.e., comprising at least 10 or 12 contiguous nucleotides).

It is also appreciated that such probes can be and are preferably labeled with an analytically detectable reagent to facilitate identification of the probe. Useful reagents include but are not limited to radioactivity, fluorescent dyes or enzymes capable of catalyzing the formation of a detectable product. The probes are thus useful to isolate complementary copies of DNA from other sources or to screen such sources for related sequences.

With respect to nucleic acid sequences which hybridize specific nucleic acid sequences disclosed herein, hybridization may be carried out under conditions of reduced stringency, medium stringency or even stringent conditions. As an example of oligonucleotide hybridization, a polymer membrane containing immobilized denatured nucleic acids is first prehybridized for 30 minutes at 45°C in a solution consisting of 0.9 M NaCl, 50 mM NaH₂PO₄, pH 7.0, 5.0 mM Denhardt's, and 0.5 0.5% SDS, 10X Na, EDTA, polyriboadenylic acid. Approximately 2 X 10' cpm (specific activity 4-9 X 108 cpm/ug) of 32P end-labeled oligonucleotide probe are then added to the solution. After 12-16 hours of incubation, the membrane is washed for 30 minutes at room temperature in 1X SET (150 mM NaCl, 20 mM Tris hydrochloride, pH 7.8, 1 mM Na₂EDTA) containing 0.5% SDS, followed by a 30 minute wash in fresh 1X SET at Tm -10°C for the oligonucleotide probe. The membrane is then exposed to autoradiographic film for detection of hybridization signals.

Stringent conditions means hybridization will occur only if there is at least 90% identity, preferably 95% identity and most preferably at least 97% identity between the sequences. See J. Sambrook et al., Molecular Cloning, A Laboratory Manual (2d Ed. 1989) (Cold Spring Harbor Laboratory) which is hereby incorporated by reference in its entirety.

"Identity" as the term is used herein, refers to a polynucleotide sequence which comprises a percentage of the same bases as a reference polynucleotide (SEQ ID NOS:1-16). For example, a polynucleotide which is at least 90% identical to a reference polynucleotide, has polynucleotide bases which are identical in 90% of the bases which make up the reference polynucleotide and may have different bases in 10% of the bases which comprise that polynucleotide sequence.

The present invention relates to polynucleotides which differ from the reference polynucleotide such that the differences are silent changes, for example, the amino acid sequence encoded by both polynucleotides is the same. The present invention also relates to nucleotide changes which result in amino acid substitutions, additions, deletions, fusions and truncations in the polypeptide encoded by the reference polynucleotide. In a preferred aspect of the invention these polypeptides retain the same biological action as the polypeptide encoded by the reference polynucleotide.

The polynucleotides of this invention were recovered from genomic gene libraries from the organisms listed in Table 1. Gene libraries were generated in the Lambda ZAP II

cloning vector (Stratagene Cloning Systems). Mass excisions were performed on these libraries to generate libraries in the pBluescript phagemid. Libraries were generated and excisions were performed according to the protocols/methods-hereinafter described.

The excision libraries were introduced into the E. colistrain BW14893 F'kan1A. Expression clones were then identified using a high temperature filter assay using phosphatase buffer containing 1 mg/ml BCIP (5-Bromo-4-chloro-3-indolyl phosphate). Expression clones encoding BCIPases were identified and repurified from the following organisms: Ammonifex degensii KC4, Methanococcus igneus KoL5, Thermococcus alcaliphilus AED112RA, Thermococcus celer, Thermococcus GU5L5, OC9a, M11TL, Thermococcus CL-2 and Aquifex VF-5.

Expression clones were identified by use of a high temperature filter assay with either acid phosphatase buffer or alkaline phosphatase buffer containing BCIP. Metcalf, et al., Evidence for two phosphonate degradative pathways in Enterobacter Aerogenes, J. Bacteriol., 174:2501-2510 (1992)).

BCIPase activity was tested as follows: An excision library was introduced into the E. Coli strain BW14893 F'kan, a pho-phh-lac strain. After growth on 100 mm LB plates containing 100 μ g/ml ampicillin, 80 μ g/ml methicillin and 1mM IPTG, colony lifts were performed using Millipore HATF membrane filters. The colonies transferred to the filters were lysed with chloroform vapor in 150 mm glass petri dishes. The filters were transferred to 100 mm glass petri dishes containing a piece of Whatman 3MM filter paper saturated with either acid phosphatase buffer (see recipe below) or alkaline phosphatase buffer (see recipe below) containing no BCIP. The dish was placed in the oven at 80-

85°C for 30-45 minutes to heat inactivate endogenous *E. coli* phosphatases. The filter bearing lysed colonies were then transferred to a 100 mm glass petri dish containing 3MM paper saturated with either acid phosphatase buffer or alkaline phosphatase buffer containing 1 mg/ml BCIP. The dish was placed in the oven at 80-85°C.

Alkaline Phosphatase Buffer (referenced in Sambrook, J. et al. (1989) Molecular Cloning, A Laboratory Manual, p. 1874) includes 100 mM NaCl, 5 mM MgCl₂ and 100 mM Tris-HCl (pH 9.5). Clones expressing phosphatase activity (when the alkaline phosphatase buffer was used) were derived from libraries derived from the organism identified above.

Acid Phosphatase Buffer includes 100 mM NaCl, 5 mM MgCl₂ and 100 mM Tris-HCL (pH 6.8). Clones expressing phosphatase activity (when the acid phosphatase buffer was used) were derived from the library derived from MllTL.

'Positives' were observed as blue spots on the filter membranes. The following filter rescue technique was used to retrieve plasmid from lysed positive colony.

Filter Rescue Technique: A pasteur pipette (or glass capillary tube) was used to core blue spots on the filter membrane. The small filter disk was placed in an Eppendorf tube containing 20 ul of deionized water. The Eppendorf tube was incubated at 75°C for 5 minutes followed by vortexing to elute plasmid DNA off the filter. Plasmid DNA containing DNA inserts from Thermococcus alcaliphilus AEDII12RA was used to transform electrocompetent E. coli DH10B cells. Electrocompetent BW14893 F'kanlA E. coli cells were used for transformation of plasmid DNA containing inserts from Ammonifex degensii KC4, Methanococcus igneus KOL5, and Thermococcus GU5L5. The filter-lift assay was repeated on

PCT/US97/10784 WO 97/48416

transformation plates to identify 'positives.' The transformation plates were returned to 37°C incubator to regenerate colonies. 3 ml of LBamp liquid was inoculated with repurified positives and incubated at 37°C overnight. Plasmid DNA was isolated from these cultures and plasmid insert were sequenced.

In some instances where the plates used for the initial colony lifts contained non-confluent colonies, a specific colony corresponding to a blue spot on the filter could be identified on a regenerated plate and repurified directly, instead of using the filter rescue technique. This "repurification" protocol was used for plasmid DNA containing inserts from the following: Ammonifex degensii KC4, Thermococcus celer, MllTL, and Aquifex VF-5.

The filter rescue technique was used for DNA from the following organisms: Ammonifex degensii KC4, Methanococcus igneus KOL5, Thermococcus alcaliphilus AED1112RA, Thermococcus CL-2, and OC9a.

Phosphatases are a group of key enzymes that remove phosphate groups from organophosphate ester compounds. The most important phosphatases for commercial purposes are alkaline phosphatases, phosphodiesterases, and phytases.

Alkaline phosphatases have several commercial applications, including their use in analytical applications as an enzyme label in ELISA immunoassays and enzyme-linked gene probes, and their use in research applications for removing 5' phosphates in polynucleotides prior to endlabeling and for dephosphorylating vectors prior to insert ligation (see also Current Protocols in Molecular Biology, (John Wiley & Sons) (1995), chapter 3, section 10).

Alkaline phosphatase hydrolyzes monophosphate esters, releasing inorganic phosphate and the cognate alcohol compound. It is non-specific with respect to the alcohol moiety, a feature which accounts for the many uses of this enzyme. The enzyme has a pH optimum between 9 and 10, however, it can also work at neutral pH. (From a study of the enzyme industry conducted by Business Communications, Co., Inc., 25 Van Zant Street, Norwalk, CT 06855, 1995.)

Two sources of alkaline phosphatase dominate and compete in the market: animal, from bovine and calf intestinal mucosa, and bacterial, from E. coli. Due to the high turnover number of calf intestinal phosphatase, it is often selected as the label in many enzyme immunoassays. usefulness of calf alkaline phosphatase is limited by its inherently low thermal stability, which is even further compromised during the chemical preparation of enzyme: antibody conjugates. Bacterial alkaline phosphatase could be an attractive alternative to calf alkaline phosphatase due to bacterial alkaline phosphatase's extreme thermotolerance at temperatures as high as 95°C. (Tomazic-Allen S.J., bacterial alkaline phosphatase Recombinant immunodiagnostic enzyme, Annales de Biologie Clinique, 1991, 49(5):287-90).

Antibodies generated against the enzymes corresponding to a sequence of the present invention can be obtained by direct injection of the enzymes into an animal or by administering the enzymes to an animal, preferably a nonhuman. The antibody so obtained will then bind the enzymes itself. In this manner, even a sequence encoding only a fragment of the enzymes can be used to generate antibodies binding the whole native enzymes. Such antibodies can then be used to isolate the enzyme from cells expressing that enzyme.

For preparation of monoclonal antibodies, any technique which provides antibodies produced by continuous cell line cultures can be used. Examples include the hybridoma technique (Kohler and Milstein, 1975, Nature, 256:495-497), the trioma technique, the human B-cell hybridoma technique (Kozbor et al., 1983, Immunology Today 4:72), and the EBV-hybridoma technique to produce human monoclonal antibodies (Cole, et al., 1985, in Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96).

Techniques described for the production of single chain antibodies (U.S. Patent 4,946,778) can be adapted to produce single chain antibodies to immunogenic enzyme products of this invention. Also, transgenic mice may be used to express humanized antibodies to immunogenic enzyme products of this invention.

Antibodies, as described above, may be employed as a probe to screen a library to identify the above-described activities or cross-reactive activities in gene libraries generated from the organisms described above or other organisms.

Example 1

Bacterial Expression and Purification of Alkaline Phosphatase Enzymes

DNA encoding the enzymes of the present invention, SEQ ID NOS:1 through 16, were initially amplified from a pBluescript vector containing the DNA by the PCR technique using the primers noted herein. The amplified sequences were then inserted into the respective pQE vector listed beneath the primer sequences, and the enzyme was expressed according to the protocols set forth herein. The oligonucleotide primer sequences used for subcloning and vectors for the respective genes are as follows:

The restriction enzyme sites indicated correspond to the restriction enzyme sites on the bacterial expression vector indicated for the respective gene (Qiagen, Inc. Chatsworth, CA). The pQE vector encodes antibiotic resistance (Amp $^{\rm r}$), a bacterial origin of replication (ori), an IPTG-regulatable promoter operator (P/O), a ribosome binding site (RBS), a 6-His tag and restriction enzyme sites.

The pQE vector was digested with the restriction enzymes indicated. The amplified sequences were ligated into the respective pQE vector and inserted in frame with the sequence

encoding for the RBS. The native stop codon was incorporated so the genes were not fused to the His tag of the vector. The ligation mixture was then used to transform the E. coli strain M15/pREP4 (Qiagen, Inc.) by electroporation. M15/pREP4 contains multiple copies of the plasmid pREP4, which expresses the lacI repressor and also confers kanamycin resistance (Kan'). Transformants were identified by their ability to grow on LB plates and ampicillin/kanamycin resistant colonies were selected. Plasmid DNA was isolated and confirmed by restriction analysis. Clones containing the desired constructs were grown overnight (O/N) in liquid culture in LB media supplemented with both Amp (100 ug/ml) and Kan (25 ug/ml). The O/N culture was used to inoculate a large culture at a ratio of 1:100 to 1:250. The cells were grown to an optical density 600 (O.D. 600) of between 0.4 and 0.6. IPTG ("Isopropyl-B-D-thiogalacto pyranoside") was then added to a final concentration of 1 mM. IPTG induces by inactivating the lacI repressor, clearing the P/O leading to increased gene expression. Cells were grown an extra 3 to 4 hours. Cells were then harvested by centrifugation.

The primer sequences set out above may also be employed to isolate the target gene from the deposited material by hybridization techniques described above.

٠.-

Example 2

Isolation of A Selected Clone From the Deposited Genomic Clones

A clone is isolated directly by screening the deposited material using the oligonucleotide primers set forth in Example 1 for the particular gene desired to be isolated. The specific oligonucleotides are synthesized using an Applied Biosystems DNA synthesizer.

The two oligonucleotide primers corresponding to the gene of interest are used to amplify the gene from the deposited material. A polymerase chain reaction is carried out in 25 μl of reaction mixture with 0.1 ug of the DNA of the gene of interest. The reaction mixture is 1.5-5 mM $MgCl_2$, 0.01% (w/v) gelatin, 20 μM each of dATP, dCTP, dGTP,-dTTP, 25 pmol of each primer and 1.25 Unit of Taq polymerase. cycles of PCR (denaturation at 94°C for 1 min; annealing at 55°C for 1 min; elongation at 72°C for 1 min) are performed with the Perkin-Elmer Cetus 9600 thermal cycler. amplified product is analyzed by agarose gel electrophoresis and the DNA band with expected molecular weight is excised and purified. The PCR product is verified to be the gene of interest by subcloning and sequencing the DNA product. The ends of the newly purified genes are nucleotide sequenced to identify full length sequences. Complete sequencing of full length genes is then performed by Exonuclease III digestion or primer walking.

Numerous modifications and variations of the present invention are possible in light of the above teachings and, therefore, within the scope of the appended claims, the invention may be practiced otherwise than as particularly described.
